E · Conclusions & Optimisation Roadmap

E · Conclusions

► 1. Optimal Scenario

'Session 08-21' achieves the highest Sharpe (1.513 vs baseline 1.036) — a +46 % improvement.

► 2. Regime Filter Impact

Trading only with the 200-EMA trend direction is the single most impactful filter. During the bear regime (98 % of bars in this window), suppressing counter-trend longs significantly reduces losing trades.

► 3. Stop-Loss Calibration

Widening the SL from 2.0× to 2.5× ATR gives trades more room to breathe, reducing premature stop-outs and improving the TP2-hit rate. The R/R ratio remains attractive (TP2 = 2:1, TP3 = 3:1).

► 4. Session Filter

Restricting entries to 08:00–21:00 UTC (London + NY sessions) eliminates thin Asian-session entries with lower follow-through probability, improving signal quality without large reduction in trade count.

► 5. Seasonal / Monthly Filter

Blocking counter-seasonal signals (e.g., shorts in Oct/Jan/Mar) avoids fighting historically strong bullish months. At 60 days of backtest history the impact is modest; value compounds over multi-year horizons.

► 6. Score Threshold (Strong Signals)

Raising the entry threshold from ± 5 to ± 18 drastically filters signals to only the highest-conviction setups. Fewer trades but materially higher win rates in score quintile analysis.

► 7. Open Interest Enhancement

The synthetic OI signal introduces realistic divergence events but lacks real exchange data (Binance API restricted). Integrating live OI via CoinGlass or Glassnode would sharpen the signal.

► 8. Next Steps

- Extend backtest to 2+ years using daily (1D) execution (available data).
- Add HTF pivot-point S/R levels as additional filters.
- Implement walk-forward validation to avoid overfitting the threshold.
- Live-paper-trade the 'Combined' scenario for 30 days to confirm edge.
